

Watershed Activity 2

Region: Eastern Coastlines

Grade Level(s): 5-8

Time Required: One 45-minute class period

Learning Objectives:

- The students will be able to demonstrate how topographical map contours model the landscape.

Materials:

- Model habitats prepared in Activity #1
- Food coloring
- A source of water
- One watering can with a sprinkle opening or other water pouring container per student team

Background:

- Shaped for thousands of years by the crashing waves and weather of the Atlantic Ocean, the eastern coastline has developed wonderfully diverse landscapes set in equally varied climates. From warmer tropical ecosystems such as Florida's beaches, barrier islands, bays, estuaries, and tidal marshes, to the colder reaches and rocky coastline of Maine, each of these landscapes has its own set of plants and animals that call these places home. These varied landscapes have developed through a combination of processes. As the sea level continues to rise due to melting of continental glaciers left by the Ice Age and the effects of climate change, most of the eastern coastal region has experienced, and continues to experience, submergence. At the same time, rivers and streams deposit sediment surrounding their mouths as they open to the ocean. In addition, the harsh waves of the Atlantic Ocean, which are weakened by the wide continental shelf jutting out into the ocean, slow and deposit the sediment that they carry near the shoreline. Thus, as glaciers melt, the ocean rises, and sediments are deposited along the shoreline. These processes have been happening concurrently for thousands of years and have marked the eastern shoreline by thick deposits of sediment and sea level rise. Those who live along this coastline must cope with its unique environmental issues. Low-lying land juxtaposed with the vast Atlantic Ocean leads to issues of flooding and erosion. These issues are compounded by the effects of climate change.

Procedures/Instructional Strategies:

1. Using the model habitats the students prepared in Activity #1, drop a couple of drops of food coloring in about two places on each team's model.
 - Explain that this is lawn fertilizer, or pollution from a chemical manufacturing

plant, or stormwater pollution (or any other type of pollutant that you choose). Each drop can be a different pollutant.

2. Tell students to use their watering cans to make it rain on their habitat again, and tell them to observe the paths of the pollutants.
3. Have the students rinse out their habitats to be used in the following activities.
4. Tell each student to write a brief constructed response to the following prompt:
 - Pretend that it is a cold winter day and there is ice on the ground. You don't want to slip so you need to put something down on the ice. Which is the most environmentally friendly choice and why: salt or sand? In your answer explain how each substance will affect the watershed and where it will end up.
5. Evaluate students with the following questions:
 - What pollutants could the food coloring represent? (Answers will vary, but could include oil, salt, gas, pesticides, herbicides, etc.)
 - Describe the pattern of runoff made by the pollutant. (The runoff made by the pollutant follows the same pattern as the water running downhill through the watershed)
 - Where does the pollutant ultimately end up? (In the Bay and then eventually the ocean)

Extensions:

- Contact the local water resources or waste permit office to see what regulations exist for the dominant industry in your watershed.
- Have students assess their homes and school to see what they are putting in the water or landfills that might leach into the groundwater. Also examine if people in the community use the landfill or if roadside dumping is the way people handle their trash. What safety precautions are used to protect the water?
- Measure trash that goes into the water in your area. To measure trash, you don't even have to wait for it to rain. Just walk along the street and see how much trash is on the sidewalk, or in the streets and gutters. All of this will end up in the watershed with the next rain.
- Measure turbidity in a nearby stream by taking two pieces of white coffee filter paper or chemistry filter paper. Designate one as the control and keep this one clean. Use a piece of brown construction paper as a second control. Assign a value of 0 to the clean filter paper and 5 to the brown construction paper. Take the second piece of filter paper and hold it in a stream or rain gutter for a few minutes. Now compare it to the controls. Is it closer in color to 0 (the filter paper) or to 5 (the construction paper)? This is an estimate of how turbid, or muddy, your water is.

National Science Education Standards:

Earth Science

- Water is a solvent. As it passes through the water cycle it dissolves minerals and gases and carries them to the oceans.
- Living organisms have played many roles in the earth system, including affecting the composition of the atmosphere, producing some types of rocks, and contributing to the weathering of rocks.
- The sun is the major source of energy for phenomena on the earth's surface, such as growth of plants, winds, ocean currents, and the water cycle. Seasons result from variations in the amount of the sun's energy hitting the surface, due to the tilt of the earth's rotation on its axis and the length of the day.

Science and Technology

- Science and technology are reciprocal. Science helps drive technology, as it addresses questions that demand more sophisticated instruments and provides principles for better instrumentation and technique. Technology is essential to science, because it provides instruments and techniques that enable observations of objects and phenomena that are otherwise unobservable due to factors such as quantity, distance, location, size, and speed. Technology also provides tools for investigations, inquiry, and analysis.
- Technological designs have constraints. Some constraints are unavoidable, for example, properties of materials, or effects of weather and friction; other constraints limit choices in the design, for example, environmental protection, human safety, and aesthetics.

Science in Personal and Social Perspectives

- When an area becomes overpopulated, the environment will become degraded due to the increased use of resources.
- Internal and external processes of the earth system cause natural hazards, events that change or destroy human and wildlife habitats, damage property, and harm or kill humans. Natural hazards include earthquakes, landslides, wildfires, volcanic eruptions, floods, storms, and even possible impacts of asteroids.
- Human activities also can induce hazards through resource acquisition, urban growth, land-use decisions, and waste disposal. Such activities can accelerate many natural changes.
- Natural hazards can present personal and societal challenges because misidentifying the change or incorrectly estimating the rate and scale of change may result in either too little attention and significant human costs or too much cost for unneeded preventive measures.
- Risk analysis considers the type of hazard and estimates the number of people that might be exposed and the number likely to suffer consequences. The results are used to determine the options for reducing or eliminating risks.
- Students should understand the risks associated with natural hazards (fires, floods, tornadoes, hurricanes, earthquakes, and volcanic eruptions), with chemical hazards (pollutants in air, water, soil, and food), with biological hazards (pollen, viruses, bacterial, and parasites), social hazards (occupational safety and transportation), and with personal hazards (smoking, dieting, and drinking).
- Individuals can use a systematic approach to thinking critically about risks and benefits.

Examples include applying probability estimates to risks and comparing them to estimated personal and social benefits.

- Important personal and social decisions are made based on perceptions of benefits and risks.
- Science influences society through its knowledge and world view. Scientific knowledge and the procedures used by scientists influence the way many individuals in society think about themselves, others, and the environment. The effect of science on society is neither entirely beneficial nor entirely detrimental.
- Societal challenges often inspire questions for scientific research, and social priorities often influence research priorities through the availability of funding for research.
- Science cannot answer all questions and technology cannot solve all human problems or meet all human needs. Students should understand the difference between scientific and other questions. They should appreciate what science and technology can reasonably contribute to society and what they cannot do. For example, new technologies often will decrease some risks and increase others.
- Scientists formulate and test their explanations of nature using observation, experiments, and theoretical and mathematical models. Although all scientific ideas are tentative and subject to change and improvement in principle, for most major ideas in science, there is much experimental and observational confirmation. Those ideas are not likely to change greatly in the future. Scientists do and have changed their ideas about nature when they encounter new experimental evidence that does not match their existing explanations.
- In areas where active research is being pursued and in which there is not a great deal of experimental or observational evidence and understanding, it is normal for scientists to differ with one another about the interpretation of the evidence or theory being considered. Different scientists might publish conflicting experimental results or might draw different conclusions from the same data. Ideally, scientists acknowledge such conflict and work towards finding evidence that will resolve their disagreement.
- It is part of scientific inquiry to evaluate the results of scientific investigations, experiments, observations, theoretical models, and the explanations proposed by other scientists. Evaluation includes reviewing the experimental procedures, examining the evidence, identifying faulty reasoning, pointing out statements that go beyond the evidence, and suggesting alternative explanations for the same observations. Although scientists may disagree about explanations of phenomena, about interpretations of data, or about the value of rival theories, they do agree that questioning, response to criticism, and open communication are integral to the process of science. As scientific knowledge evolves, major disagreements are eventually resolved through such interactions between scientists.
